4	AVL Trees	6
5	2-3 Trees, Red-Black Trees, AA Trees	9
5.1	2-3 Trees	9
5.2	Red-Black Trees	10

1 Lists

```
init() => initializes list
get(i) => returns element at index i
set(i, x) => sets ith element to x
length() => returns number of elements in the list
insert(i, x) => insert x prior to element a_{i} (shifts indices after)
delete(i) => deletes ith element (shift indices after)
```

Sequential Allocation (Array): when array is full, increase its size but a constant factor (e.g. 2). Amortized array operations still $O(1)$

Linked Allocation (Linked List)

Stack(push, pop): on one end of the list

Queue(enqueue, dequeue): insert at tail (end) and remove from head (start)

Deque(combo stack and queue): can insert and remove from either ends of list

Multilist: multiple lists combined in an aggregate structure (e.g. ArrayList)

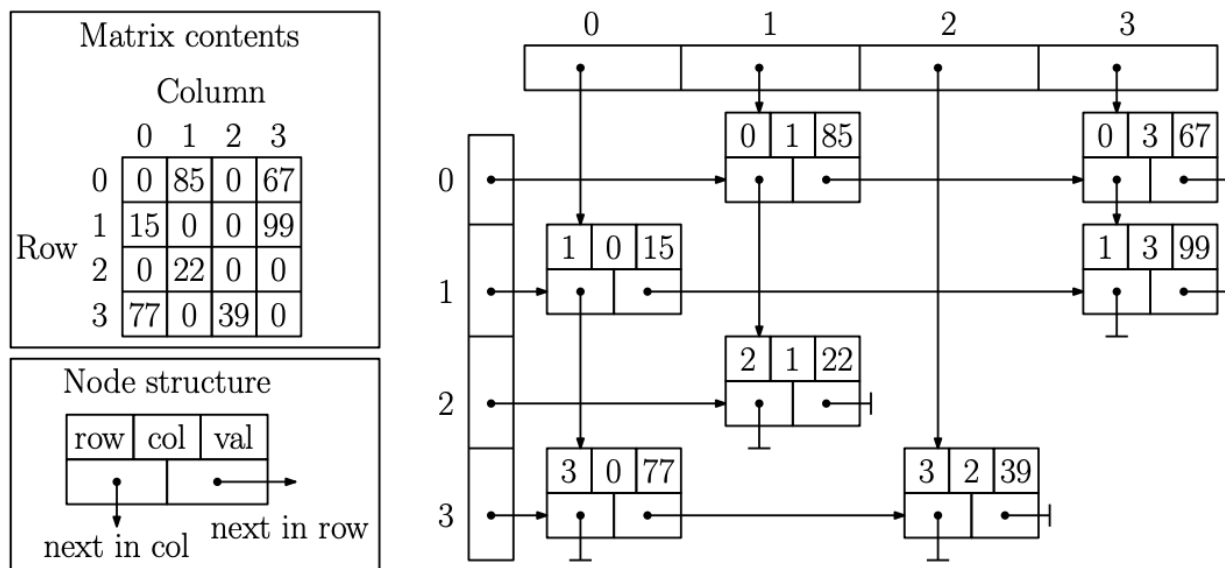

Fig. 2: Sparse matrix representation using a multilist structure.

Sparse Matrix: create $2n$ linked lists for each row and col

Each entry stores a row index, col index, value, next row ptr, and next col ptr

2 Trees

Free Tree: connected, undirected graph with no cycles (like MST)

Root Tree: each non-leaf node has ≥ 1 children and a single parent (except root)

Aborecence = out-tree Anti-arborescence = in-tree

Depth = max # of edges of path from root to a node

One way to represent tree is to have a pointer to first child and then a pointer to next sibling

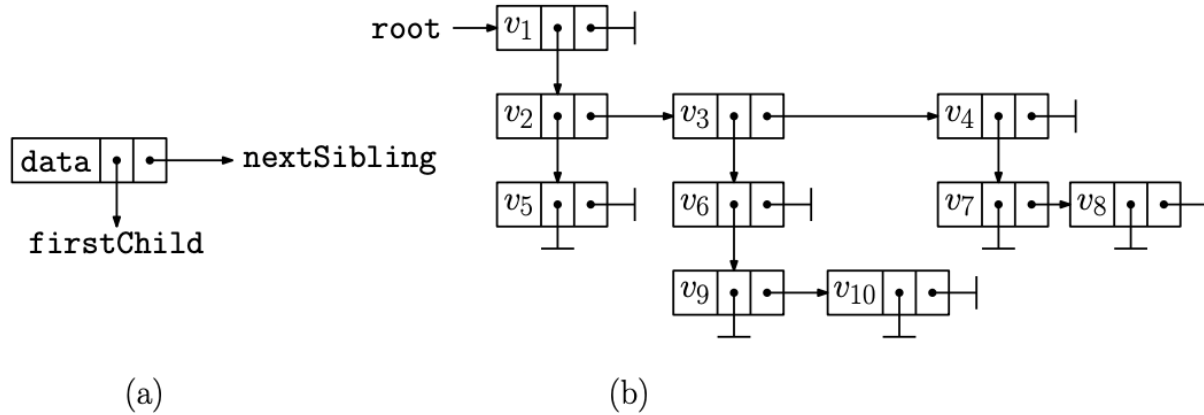

Fig. 3: Standard (binary) representation of rooted trees.

Binary Tree: rooted, ordered tree where each non-leaf node has 2 possible children (left, right)

Full Tree: All nodes either have 0 children or 2 children

Can make full binary tree by extending tree by adding external nodes to replace all empty subtrees

Fig. 4: Binary trees: (a) standard definition, (b) full binary tree, (c) extended binary tree.

```

class BinaryTreeNode<E> {
    private E entry;
    private BinaryTreeNode<E> left;
    private BinaryTreeNode<E> right;
    ...
}

```

In-order traversal: left, root, right

Pre-order traversal: root, left, right

Post-order traversal: left, right, root

If there are n internal nodes in an extended tree, there are $n+1$ external nodes

Proof by induction: Extended tree binary tree with n internal nodes has $n+1$ external nodes has $2n+1$ total nodes

Let $x(n)$ = number of external nodes given n internal nodes and prove $x(n) = n + 1$

Base Case $x(0) = 1$ a tree with no internal nodes has 1 external node

IH: Assume $x(i) = i + 1$ for all $i \leq n - 1$

IS: let n_L and n_R be the number of nodes in Left and Right subtrees

$x(n) = (n_L + 1) + (n_R + 1) = (1 + n_L + n_R) + 1 = n + 1$ external nodes

so $n + 1$ (external) + n (internal) = $2n + 1$

Moreover, about $1/2$ of nodes of extended Binary Tree are leaf nodes

Threaded Binary Tree: Give null pointers information about where to traverse next

If left-child = null then stores reference to node's inorder predecessor

If right-child = null then stores references to node's inorder successor

Fig. 6: A Threaded Tree.

```

BinaryTreeNode inorderSuccessor(BinaryTreeNode v) {
    BinaryTreeNode u = v.right;
    if(v.right.isThread) return u;
    while(!u.left.isThread) u = u.left;
    return u;
}

```

if v 's right-child is a thread, then we follow thread.

Otherwise go through v 's right child and iterate through left-child links

Complete Binary Tree: represented using sequential allocation (array) because no space is wasted

number of nodes is inbetween 2^h and $2^{h+1} - 1$

```

leftChild(i): if(2i <= n) then 2i else null;
rightChild(i): if (2i + 1 <= n) then 2i + 1 else null;
parent(i): if (i >= 2) then [i/2] else null;

```

3 Dictionaries

```
void insert(Key x, Value v) => if key exists, exception is thrown
void delete(Key x) => if key does not exist, exception thrown
Value find(Key x) => return value associated with key or null if not found
```

Array representation:

Unsorted array has $O(n)$ search and delete, $O(1)$ insert although we need $O(n)$ to check for duplicates

Sorted Array has $O(\log n)$ search and $O(n)$ insertion and deletion

Binary Search Tree Representation (left < root < right):

```
//Recursive
Value find(Key x, BinaryNode p) {
    if (p == null) return null;
    else if (x < p.key) return find(x, p.left);
    else if (x > p.key) return find(x, p.right);
    else return p.val;
}

//Iterative
Value find(Key x) {
    BinaryNode p = root;
    while(p != null) {
        if (x < p.key) p = p.left;
        else if (x > p.key) p = p.right;
        else return p.value;
    }
    return null;
}
```

$O(n)$ search for degenerate tree, $O(\log n)$ search for balanced tree

Can use extended BST to give info that target key is inbetween inorder predecessor and inorder successor

Insert: search for key and if found throw exception else we hit a null and insert there

```
BinaryNode insert(Key x, Value v, BinaryNode p) {
    if (p == null) p = new BinaryNode(x, v, null, null);
    else if (x < p.key) p.left = insert(x, v, p.left);
    else if (x > p.key) p.right = insert(x, v, p.right);
    else throw DuplicateKeyException;
    return p;
}
```

Either tree is empty so return new node or we return the root of the original tree with the added node

$O(n)$ insert for degenerate tree, $O(\log n)$ insert for balanced tree

Delete find a replace with inorder successor (aka leftmost on right subtree)

```
BinaryNode delete(Key x, BinaryNode p) {
    if (p == null) throw KeyNotFoundException;
    else
        if (x < p.data)
            x.left = delete(x, p.left);
        else if (x > p.data)
            x.right = delete(x, p.right)
        else if (p.left == null || p.right == null)
            if (p.left == null) return p.right;
            else return p.left;
        else
            r = findReplacement(p);
}
```

```

        //copy r's contents to p
        p.right = delete(r.key, p.right);
    }

    BinaryNode findReplacement(BinaryNode p) {
        BinaryNode r = p.right;
        while(r.left != null) r = r.left;
        return r;
    }

```

$O(n)$ deletion for degenerate tree, $O(\log n)$ deletion for balanced tree height of BST on average will be $\ln(n)$
 Proof: for $i = 2$ to n , insert elements into BST and look at depth of left most node (min value)
 chance that a number is the min is $\frac{1}{i}$ so Expected Height is $\sum_{i=2}^n \frac{1}{i} \approx \ln(n)$

4 AVL Trees

Balance Condition: For every node in tree, absolute difference between heights of left and right subtrees is at most 1
 Worst case height can be shown to be $O(\log n)$ using Fibonacci sequence

$F_h \approx \varphi^h \sqrt{5}$ where $\varphi = (1 + \sqrt{5})/2$

let $N(h)$ denote minimum number of nodes in any AVL tree of height h .

$N(0) = 1, N(1) = 2, N(h) = 1 + N(h_L) + N(h_R) = 1 + N(h-1) = N(h-2)$

if a given node has height h , one of its subtrees must have height $h-1$, and to make it have min # of nodes, the other subtree has height $h-2$

Now $N(h) = n \geq c\varphi^h \rightarrow h \leq \log_{\varphi} n \rightarrow O(\log n)$

Also find method using AVL is $O(\log n)$

Rotations are used to main tree's balance by modifying relation between two nodes but preserving the tree's inorder properties

```

    BinaryNode rotateRight(BinaryNode p) {
        BinaryNode q = p.left;
        p.left = q.right;
        q.right = p;
        return q; // q is now root
    }

    Binary Node rotateLeft(Binary Node p) {
        BinaryNode q = p.right;
        p.right = q.left;
        q.left = p;
        return q; // q is now root
    }

```

Fig. 3: (Single) Rotations. (Triangles denote subtrees, which may be null.)

Single rotations work when the imbalance occurs on the outer edges of the tree. Need to use double rotations LR or RL to balance inner trees

Fig. 4: Double rotations (`rotateLeftRight(p)` and `RotateRightLeft(p)`).

Insertion works similar to BST except we update the heights of subtrees and apply rotations to maintain height
When insertion occurs balance factors of ancestors is altered by ± 1

If a node has a balance factor that violates Balance Property:

- Left-Left subtree too deep then rotate right
- Right-Right subtree too deep then rotate left
- Left-Right subtree too deep then rotate left-right
- Right-Left subtree too deep then rotate right-left

```
int height(AvlNode p) return p == null ? -1 : p.height;
void updateHeight(AvlNode p) p.height = 1 + max(height(p.left), height(p.right));
int balanceFactor(AvlNode P) return height.(p.right) - height(p.left);
AvlNode rotateRight(AvlNode p) {
    AvlNode q = p.left;
```

```

    p.left = q.right; // swap inner child
    q.right = p;      // bring q above p
    updateHeight(p);
    updateHeight(q);
    return q;        // q replaces p
}
AvlNode rotateLeft(AvlNode p) {... symmetrical to rotateRight ...}
AvlNode rotateLeftRight(AvlNode p) {
    p.left = rotateLeft(p.left);
    return rotateRight(p);
}
AvlNode rotateRightLeft(AvlNode p) {... symmetrical to rotateLeftRight ...}
AvlNode insert(Key x, Value v, AvlNode p) {
    if (p == null) p = newAvlNode(x, v, null, null);
    else if (x < p.key) p.left = insert(x, v, p.left);
    else if (x > p.key) p.right = insert(x, v, p.right);
    else throw DuplicateKeyException;
    return rebalance(p);
}
AvlNode rebalance(AvlNode p) {
    if (p == null) return p;
    if (balanceFactor(p) < -1) {
        if (height(p.left.left) >= height(p.left.right)) { //left-left heavy
            p = rotateRight(p);
        } else { //left-right heavy
            p = rotateLeftRight(p);
        }
    }
    else if (balanceFactor(p) > 1) {
        if (height(p.right.right) >= height(p.right.left)) { //right-right heavy
            p = rotateLeft(p);
        } else { //right-left heavy
            p = rotateRightLeft(p);
        }
    }
    updateHeight(p);
    return p;
}
}

```

Deletion works in a similar manner in that we call normal BST delete and then rotate as necessary. However we need to call rebalance on further ancestors to check balance condition

5 2-3 Trees, Red-Black Trees, AA Trees

5.1 2-3 Trees

All leaves are on the same level

nodes can either be 2-node (normal binary tree) or 3-node (2 keys b, d and 3 branches A, C, E where $A < b < C < d < E$)

Fig. 1: (a) 2-node, (b) 3-node, and (c) a 2-3 tree.

Recursively defined as:

empty (null)

root is 2-node and has two 2-3 subtrees of equal height

root is 3-node and has three 2-3 subtrees of equal height

Sparsest 2-3 tree is a complete binary tree

Height is $O(\log n)$

Find: recursive descent but when 3-node is reached, compare x with both keys to find which branch to go to

Insertion: search for key and insert like in a normal tree.

if parent is a 2-node, now it is a 3-node with a null subtree

if parent is 3 node then it becomes 4-node and we have to fix it by splitting the 4-node into two 2-nodes and prop the middle term up for recursion

Will continue to recurse up until it reaches the root

Fig. 2: 2-3 tree insertion: (a) splitting a 4-node into two 2-nodes and (b) creating a new root.

Deletion: find and replace target with inorder successor and then delete the leaf

If parent of leaf is a 3-node then parent becomes a 2-node and done

If parent is a 2-node then it becomes a 1-node (0 keys, 1 subtree) so we can do

Adoption: if sibling is a 3-node then adopt a key and a subtree so we have two 2-nodes

Merge: merge 1-node and 2-node and take a key from parent then recurse up. If root is reached, remove it and make a child the root

5.2 Red-Black Trees

Take AVL 3-node and create a 2-node combo by using d, C, E as the right subtree and b, A for left subtree
Color created right subnode red and all other nodes black, creating a binary tree
